**Gasoline Dispensing Facility (GDF)  
Low Permeation Hose Upgrade Cost Report**

Prepared By:

Jason McPhee, P.E.

Evaporative Controls and Certification Branch  
Monitoring and Laboratory Division

July 15, 2008

Revised July 9, 2010

## **Introduction**

In June of 2007, the California Air Resources Board (CARB) staff conducted a survey of manufacturers of gasoline dispensing facility (GDF) hoses to determine the cost to upgrade current GDF hoses in California to include low permeation hose technology. CARB staff requested projected cost increases for both balance and vacuum assist styles of vapor recovery hoses and conventional (non-vapor recovery) hoses. The survey criteria for low permeation hoses included that the hoses would be approximately 10 feet in length and would permeate at a rate of no more than 5 g/m<sup>2</sup>/day when tested at a constant temperature of 40 °C with CE-10 test fuel. Subsequent hose testing with manufactures involved in the survey has shown prototypes capable of meeting a slightly less rigorous standard of 10 g/m<sup>2</sup>/day when tested at a constant temperature of 38 °C with CE-10 test fuel.

Staff also collected quotes from three different distributors of GDF hoses in order to estimate actual consumer costs of current vacuum assist, balance, and conventional hoses.

From the survey, staff concluded that the cost to upgrade either a vacuum assist style hose or a conventional vapor recovery hose would be approximately \$10. Staff found that a balance style vapor recovery hose upgrade would be approximately \$29. Staff estimates that the cost of these upgrades would lead to price increases of current products: 9% for vacuum assist hoses, 26% for conventional hoses, and 15% for balance hoses. Due to the higher cost increase to upgrade a balance style hose, CARB staff is proposing performance standards for vacuum assist and conventional hoses at this time. Balance style hoses will not be subject to this regulation.

## **Background**

It is part of CARB's mission to promote and protect the public health and welfare through the effective and efficient reduction of air pollutants. In carrying out this mission, CARB has sought to control hydrocarbon emissions at GDFs in California since 1975. Hydrocarbon emissions are reactive organic gases which can react in the atmosphere to form photochemical smog. Recently, CARB staff has identified GDF hoses as a sources of uncontrolled reactive organic gas emissions due to gasoline's ability to permeate through common GDF hose materials.

California GDFs, which are permitted by the local air pollution control districts, in most cases must use vapor recovery style hoses. Vapor recovery hoses are different from conventional fuel delivery hoses in that they have two paths: one for fuel delivery and the other for vapor return. There are two different styles of vapor recovery hoses: balance and vacuum assist. For permeation purposes, vacuum assist hoses are similar to standard fuel delivery hoses in that the liquid fuel is carried against the inside of the outer hose wall. Balance hoses are different, carrying vapor against the outer hose wall (Figure 1).

Figure 1 Cutaways of vapor recovery GDF hose showing vapor and liquid paths.

A common form of low permeation technology for fuel delivery hoses is the application of a barrier layer to the hose. The barrier layer is usually a material with a much lower permeation rate than the hose material which it is being added to. It is generally applied as an internal layer or the inner most layer of multi-layer hoses. It is generally a thinner layer than that of the hose it is being added to and it is generally more costly. CARB has certified over 60 such low permeation fuel delivery hoses for its small off road engine (SORE) program alone.<sup>1</sup>

### Current GDF Hose Prices

To better understand the significance of the estimates received in this survey, staff requested quotes on two different makes of vacuum assist, balance, and conventional hoses from three different distributors of GDF hoses that are representative of those currently in use. In all, staff received five quotes for each type hose. The results of this investigation can be seen in Table 1.

Table 1: 2007 Hose Prices

Hose Type	Average Price	Median Price	Models Quoted	Total Quotes Obtained
Balance with Liquid Removal	\$194.60	\$196.54	2	5
Vacuum Assist	\$110.64	\$111.54	2	5
Conventional (Non-Vapor Recovery)	\$37.81	\$37.86	2	5

## **The Survey**

As part of the effort to quantify the cost effectiveness of applying low permeation hose technology to GDF hoses, staff conducted the 2007 survey (Attachment 1) discussed in this report. The hose manufacturers that were surveyed by ARB staff include; FLEX-ING, Gates Corporation, Goodyear Tire & Rubber Company, HBD/Thermoid Inc., OPW Fueling Components, Parker Hannifin, and Vapor Systems Technologies Inc.

Staff has also been participating in testing of low permeation hose technology in conjunction with Underwriter's Laboratory (UL) and the above listed manufacturers. This testing has demonstrated several GDF hoses that can meet a permeation standard of 10 g/m<sup>2</sup>/day at a constant temperature of 38 °C with CE-10 test fuel. Although this standard is slightly less rigorous than that mentioned in the survey (Attachment 1), it is a very large reduction from current GDF hoses, which for the same testing conditions have been shown to permeate at rates of over 300 g/m<sup>2</sup>/day during the same UL testing. Given these testing results, staff is very confident that the numbers submitted in the survey reflect careful consideration by the companies involved in the survey.

On the outset of this survey, staff agreed with manufacturers to keep numbers reported by participants confidential by not tying specific numbers to individual companies. Staff agreed to this restriction in order to gain the sensitive marketing information necessary to conduct this analysis. Further, due to low responses for some categories, staff will only discuss the averages of the submittals each category so as not to give a competitor of companies that submitted cost estimates an unfair insight into those companies' business costs/projections.

## **Survey Response**

All seven of the GDF hose manufacturers contacted for this survey submitted responses. However, two were rejected completely. One was rejected as the cost increases submitted by that respondent were an extreme outlier, being above the average of the other submittals by a factor of more than 10. The other was rejected as the company refused to supply actual dollar figures, submitting only percentages. As mentioned previously, for confidentiality reasons, staff will not discuss the specifics of the submitted numbers further.

## **Conventional (Non-Vapor Recovery) Hose Survey Results**

The cost increase estimates for adding low permeation technology to conventional GDF hoses are displayed in Table 2. One participant (Participant A) felt that their existing product would meet the permeation requirements given in the survey. This is evidenced by the zeros in the minimum column of Table 2. However, Participant A's existing product cost was more expensive than the average of the

existing product costs of the other respondents. In order to correct for this, staff subtracted the average of the current manufacturer and end-user costs of current products of the other respondents from Participant A's current manufacturing and end-user costs. These differences were then applied as Participant A's cost increases. The averages\* and medians\* given in Table 2 reflect this correction.

**Table 2: Low permeation cost increase for conventional hoses.**

	Average*	Median*	Maximum	Minimum
Manufacturing Cost Increase	\$5.52	\$5.78	\$6.15	\$0.00
Cost Increase to Consumer	\$9.89	\$10.00	\$17.72	\$0.00

In applying the average cost increase to consumers of \$9.89 given in Table 2 to the 2007 conventional hose price of \$37.86 given in Table 1, the average cost increase as a percentage of current product costs is calculated to be 26 %.

### **Vacuum Assist Hose Survey Results**

Although staff received less estimates for vacuum assist hose cost increases than for conventional hose, those that did respond noted to CARB staff that the technology applied to conventional hoses would be the same as that applied to vacuum assist hoses. Those respondents who submitted cost increases in both categories applied the same cost increases for vacuum assist and conventional hoses. Staff believes this is valid because the outer hose from which permeation would be controlled is essentially the same hose as a conventional hose with different fittings. Therefore, staff is applying the cost increase generated for conventional hoses of \$9.89, as given in Table 2, as the vacuum assist hose cost increase to end-users. This leads to a cost increase of 9% from the original product price of \$110.64, as given in Table 1.

### **Balance Hose Survey Results**

Due to the low number of responses on this category, and the need for confidentiality, staff cannot provide as much information as provided in the previous categories. Because balance outer hoses are dissimilar from that of vacuum assist hoses (see Figure 1) and conventional hoses, assumptions about cost increases cannot be drawn directly from the conventional hose survey results as with vacuum assist hoses. Further, staff has not yet seen a prototype for low permeation balance hose.

The average cost increase from the survey for upgrading balance hoses with low permeation technology was \$29.07. This leads to a cost increase of 15% from the original product price of \$194.60, as given in Table 1. The higher cost is likely due

to the balance hose's exotic design of having a metal helix inside of the hose material running the length of the hose. This leads to a corrugated profile.

## **Conclusion**

Based upon the survey results and evidence collect through testing at Underwriter's Laboratory, CARB staff concludes that it is possible to upgrade GDF hoses with low permeation technology such that a hose 10 feet in length would permeate at a rate of no more than 10 g/m<sup>2</sup>/day when tested at a constant temperature of 38 °C with CE-10 test fuel. Staff believes that the costs of meeting this standard would be approximately \$10 for either a conventional hose or a vacuum assist style vapor recovery hose, and approximately \$29 for a balance style vapor recovery hose. Staff estimates that the cost of these upgrade would lead to price increases of current products for these styles of hose of; 9% for vacuum assist hoses, 15% for balance hoses, and 26 % for conventional styles of hoses.

To: Gasoline Dispensing Facility (GDF) Hose Manufacturers

The purpose of this letter is to request your help in collecting manufacturing cost information for low permeation GDF hoses. In March, 2005, the California Air Resources Board (ARB) conducted a cost effectiveness survey on low permeation GDF hoses, which specified a permeation limit of 2-5 g/m<sup>2</sup>/day when tested with California commercial pump fuel at 28°C. ARB is now attempting to re-evaluate cost effectiveness estimates to reflect the current, more stringent, permeation standard that ARB is considering. Therefore, ARB is asking GDF hose manufacturers for an estimate on the manufacturing cost increase involved in producing GDF hose given the following parameters:

- The hose length is approximately 10 ft.
- The permeation standard is a maximum of 5 g/m<sup>2</sup>/day.
- The test is performed at a constant temperature of 40°C.
- The test fuel is CE-10.

Please assist ARB in this endeavor by filling in the applicable sections of the enclosed survey.

Upon request, the source of the information provided to ARB regarding the enclosed survey can be kept confidential. Any confidential or proprietary information submitted will be handled in accordance with title 17 California Code of Regulations section 9100, which specifies the requirements for handling confidential information submitted to public agencies. The cost information provided will be used to help evaluate the cost effectiveness of setting permeation standards for GDF hoses.

If you have any questions concerning this request, please contact Jason McPhee at (916) 322-8116 or via email at [jmcphee@arb.ca.gov](mailto:jmcphee@arb.ca.gov), or contact me at (916) 327-1282 or via email at [jwatson@arb.ca.gov](mailto:jwatson@arb.ca.gov).

Sincerely,

Jim Watson, Manager  
Engineering Development and Testing Section  
Monitoring and Laboratory Division

# Gasoline Dispensing Facility (GDF) Hose Upgrade Cost Survey

Purpose: The California Air Resources Board (ARB) is attempting to re-evaluate cost effectiveness estimates to reflect the current permeation standard that ARB is considering for GDF hose. Therefore, ARB is asking GDF hose manufacturers for an estimate on the manufacturing cost increase involved in producing GDF hose that will meet this permeation standard. Please assist ARB in this endeavor by filling in the applicable sections of this survey.

Date: \_\_\_\_\_

Company Name: \_\_\_\_\_

Please note that any reference to the term "permeation standard" in this survey refers to GDF hose that meets the general permeation hose parameters listed below.

**General Permeation Hose Parameters:**

- 1) The hose length (unit size) is approximately 10 ft.
- 2) The permeation standard is a maximum of 5 g/m<sup>2</sup>/day.
- 3) The test is performed at a constant temperature of 40°C.
- 4) The test fuel is CE-10.

Please fill in the table below. All costs are per unit, referring to a 10 ft. section of hose complete with end-fittings.

GDF Hose Type	Manufacturing Cost of Current Product	Manufacturing Cost Increase to Meet Permeation Standard	Final Manufacturing Cost to Meet Permeation Standard	End-User Cost of Current Product	End-User Cost Increase to Meet Permeation Standard	Final End-User Cost to Meet Permeation Standard
Balance	\$	\$	\$	\$	\$	\$
Vacuum Assist	\$	\$	\$	\$	\$	\$
Non-Vapor-Recovery	\$	\$	\$	\$	\$	\$

Comments and additional relevant GDF hose cost information : \_\_\_\_\_
